

Web Typography – Adaptive Designs

By: Debra Breed

Release: 5/12/2026

Not too long ago, website design could focus on Desktop applications. Many applications over the past decade have had mobile-adaptive design technologies built in, but this was automatic and given little thought.

Today, mobile adaptation is equally important and should influence the workstation or laptop approach, making design a bit more challenging. In 2025, mobile access to websites surpassed desktop applications. Currently, 54% of websites are viewed on mobile phones according to gs.statcounter.com. I can share from personal experience in Asia that mobile use is even higher, some months over 70%.

To provide some examples, we examined typography on two websites across laptop and mobile designs.

The first site, B-egg Farm (b-egg.farm), uses a vertical, single-column approach that does not adapt well to mobile design.

You may notice that the typical navigation is missing; the same is true for the mobile site. The small hamburger menu in the upper-left corner links to a “Home” page that displays the site's menu. The approach is unique but may be less intuitive.

The overall font selection for the site is good, but there are many instances where contrast could be improved. Contrast issues like white or yellow type on a light background, and a multi-colored explosion that looks interesting and is eye-catching, but is also hard to read, especially on the mobile site. The custom font created for branding stands out strongly throughout the site.

Overall, this simple approach, using only egg-like colors, really helps the brand to stand out. The mobile design for this site worked, as did the laptop design. The only real annoyance was that the site showed a U.S.-based address with a European phone number, and all the measurements were metric. The metric was fine, but the site seemed focused on increasing sales in the United States, so having Imperial translations may have helped culturally.

The second site reviewed was TagTeamSigns (tagteamsigns.com). Under the company name, it does say DESIGN • BUILD • INSTALL. There is little evidence of design work or capability on the site.

The design is BOLD, a lot of stuff in capital letters, and the color is vibrant, but both overwhelm.

Additionally, pure red is the number one color to avoid for people with vision impairment, as it may appear dark gray or black.

Swapping out the red color may earn some design credit for the Services page.

The layout is clean and looks identical on the mobile page.

Then, the “Who We Are” page appears. Here we have a new font thrown in, an annoying background picture, and now red text. Well, at least it is not all in capitals.

The next Page is their work, it began with the famous red backdrop and a couple of sentences on their greatness and latest tech. But then they decided to add this collage. Well, it is a bit smashed together on the laptop, but on the phone, it is a complete mess that runs on forever. It would have been better to eliminate all the red and share pictures throughout the site, maybe cleaning them up a bit to emphasize their true work and the type of signs shown.

My final issue with this site was its location. Based on the phone number, it looks like Phoenix, Arizona. Their Google listing is the same, with no location. Maybe they are looking for work outside of Arizona, who knows? They never say.

This was the comparison of extremes in website designs. I was a little surprised that neither site offered a language option. Maybe they assume Google will do the job and convey the same meaning? In Phoenix, 30% of residents speak Spanish as their first language; in the United States, about 25% do, according to Gemini AI. Does a Google translation convey the right emotions or messages? Did they ask their target audience of Spanish speakers?

We hope you enjoyed it!
